## I. INTRODUCTION

**S**tart explaining the initial problem

## II. METHODS

Parlare dei metodi di ABC e di Maximal coupling (con time average) in modo separato.  
poi parlare qua di come siano stati messi insieme o nella sezione dopo?

### i. Unbiased Markov chain Monte Carlo methods with couplings

Markov chain Monte Carlo (MCMC) methods provide consistent approximations of high dimensional integrals, namely as the number of iterations goes to infinity. However, these estimators can be potentially biased for any fixed number of iterations, hence the aim is to propose a general construction to produce unbiased estimators of integrals with respect to a target probability distribution.

Glynn and Rhee [?] illustrated a construction on Markov chains represented by iterated random functions; in their approach only two chains must be coupled for the proposed estimator to be unbiased, without further assumptions on the state space or target distribution.

The goal is to estimate

$$\mathbb{E}_{\pi}[h(X)] = \int h(x)\pi(dx).$$

The estimator is based on a coupled pair of Markov chains,  $(X_t)_{t \geq 0}$  and  $(Y_t)_{t \geq 0}$ , which marginally start from  $\pi_0$  and evolve accordingly to  $P$ .

It must be considered some assumptions:

1. as  $t \rightarrow \infty$ ,

$$\mathbb{E}[h(X_t)] \rightarrow \mathbb{E}_\pi[h(X)];$$

and there exists  $\eta > 0$  and  $D < \infty$  such that  $\mathbb{E}[|h(X_t)|^{2+\eta}] \leq D$  for all  $t \geq 0$ ;

2. the chains are such that the meeting time

$$\tau = \inf\{t \geq 1 : X_t = Y_{t-1}\}$$

satisfies  $\mathbb{P}(\tau > t) \leq C\delta^t$  for all  $t \geq 0$ , for some constants  $C < \infty$  and  $\delta \in (0, 1)$ ;

3. the chains stay together after meeting:

$$X_t = Y_{t-1} \forall t \geq \tau.$$

Thanks to the previous assumptions it can be proved that:

$$\mathbb{E}_\pi[h(X)] = \mathbb{E}[h(X_k) + \sum_{t=k+1}^{\tau-1} \{h(X_t) - h(Y_{t-1})\}];$$

and the Rhee–Glynn estimator can be defined as:

$$H_k(X, Y) = h(X_k) + \sum_{t=k+1}^{\tau-1} \{h(X_t) - h(Y_{t-1})\}$$

which is unbiased by construction.

time-averaged estimator:

$$H_{k:m}(X, Y) = \text{MCMC}_{k:m} + \text{BC}_{k:m}$$

where:

$$\text{MCMC}_{k:m} = \frac{1}{m-k+1} \sum_{l=k}^m h(X_l)$$

is the standard MCMC average;

$$\text{BC}_{k:m} = \sum_{l=k+1}^{\tau-1} \min(1, \frac{l-k}{m-k+1}) \{h(X_l) - h(Y_{l-1})\}$$

is the bias correction.

The algorithm of the time-average estimator:

1. draw  $X_0$  and  $Y_0$  from an initial distribution  $\pi_0$  and draw  $X_1 \sim P(X_0, \cdot)$ ;
2. set  $t = 1$ : while  $t < \max\{m, \tau\}$  and:
  - a draw  $(X_{t+1}, Y_t) \sim \bar{P}\{(X_t, Y_{t-1}), \cdot\}$ ;
  - b set  $t \leftarrow t + 1$ ;
3. compute the time-averaged estimator:

$$H_{k:m}(X, Y) = \frac{1}{m-k+1} \sum_{l=k}^m h(X_l) + \sum_{l=k+1}^{\tau-1} \min(1, \frac{l-k}{m-k+1}) \{h(X_l) - h(Y_{l-1})\}.$$

First name	Last Name	Grade
John	Doe	7.5
Richard	Miles	2

Metropolis–Hasting algorithm allow us to calculate the coupled kernel  $\bar{P}\{(X_t, Y_{t-1}), \cdot\}$ :

1. sample  $(X^*, Y^*)|(X_t, Y_{t-1})$  from a maximal coupling of  $q(X_t, \cdot)$  and  $q(Y_{t-1}, \cdot)$ ;
2. sample  $U \sim \mathcal{U}([0, 1])$ ;
3. if

$$U \leq \min \left\{ 1, \frac{\pi(X^*)q(X^*, X_t)}{\pi(X_t)q(X_t, X^*)} \right\}$$

then  $X_{t+1} = X^*$ ; otherwise  $X_t = X_{t-1}$ ;

4. if

$$U \leq \min \left\{ 1, \frac{\pi(Y^*)q(Y^*, Y_t)}{\pi(Y_t)q(Y_t, Y^*)} \right\}$$

then  $Y_{t+1} = Y^*$ ; otherwise  $Y_t = Y_{t-1}$ .
